1 Project Assignment 1

1

1 Project Assignment 1

1.1 Assignment Overview

The goal of this team project is to propose a mechanism design that is interesting, grounded in physical reality, and relevant to the course material. This year, we will be focusing on *bio-inspired solutions* for **terrestrial locomotion**. Your task is to develop and study a mechanism composed of:

- *Planar mechanisms*, such as four and five-bar mechanisms
- *Spherical mechanisms*, such as *spherical* four or five-bar mechanisms
- Sarrus linkages or other straight-line mechanisms.

The source of bioinspiration can be extant(living) or extinct, but you should be able to find enough information about it to make a set of reasonable assumptions about what you don't know. Focus on an animal in a size range that you can make at scale, at a reasonable cost, rather than scaling a different-sized animal up or down. The project is thus broken into several parts:

- **Project Goal and Fit:** Select a research topic that is interesting to you and worth pursuing, and defend your decision.
- **Background Research** Start thinking about the scale of your robot, how to use the motion, behavior, or morphology of biological systems to inspire your design, and how knowledge of biomechanics can inspire a mechanism design.
- **Initial Calculations**
- **Specifications generation.**
- **Mechanism Design**
- **Modeling and Analysis:** Use your knowledge of the mechanism's motion to estimate the forces, and torques, power requirements, and speed of your system.

Please read this whole assignment first.

The following team assignment may be completed and submitted as a group on Canvas. Please work with your group to complete all parts.

1.2 Instructions

1. Discuss and decide on the goals of your project as a team. Write down your team's goal.

1. Identify a candidate organism you wish to focus on. This consists of a specific animal species, its body plan, and the motion of interest. Search in Google scholar, using keywords such as "anatomy", "morphology", "mechanics", "biomechanics", "ground reaction forces", etc. along with the animal's informal or scientific name along with the type of locomotion.
2. What would you like to do with this animal? Study some particular aspect? Answer a particular research question? Design a product that addresses a particular need observed?

Please check with Dr. Aukes if you need further clarification / approval.

3. Explain your rationale for why it is a good question to ask by answering the following questions. For each numbered answer provide *at least one paragraph per response*.

1. **Scope:** Discuss your plan for constraining the problem to ensure your project can be designed and built within the scope of one semester.

Examples include looking at one specific type of motion, using a specific animal as a source of inspiration (for generating unique specifications), or limiting yourself to a particular set of materials, parts, cost requirements, etc.

2. **Impact:** Is your project interesting, timely, relevant, or important?

Some ways you could answer this question would be by answering one or more of the following questions:

- What makes it important to others?
- Why is this idea important now? What prevented it from being answered 10 years ago?
- Within what contexts could other people use your results?
- What are the potential broader impacts on society?

3. **Team Fit:** How does answering this question leverage your interests and abilities?

4. **Topic Fit:** How does the question use foldable robotics techniques to answer it?

2. Perform Background Research.

1. Search for existing research papers (using google scholar or similar) on the same animal, subsystem, and motion, as well as robots inspired by this animal or gait.
2. Identify *four* citations about your selected animal and/or bio-inspired robots based on the same animal, subsystem, and/or motion that will be most helpful in establishing critical design criteria.
3. Collect key information about your organism or its robotic counterpart.

Examples of the types of information to include:

- Typical mass of the animal as a whole, or as the sum of key anatomical parts.
- Average speed of the animal.
- Key points in a stride: leg motion such as stride length and maximum foot height, trunk motion and orientation, etc.
- Typical ground reaction forces during locomotion (a plot is best, so include that as well below the table)
- Metabolic energy/power consumed to locomote (respiration).
- Mechanical energy/power generated during locomotion
- Key biological materials and their mechanical properties (bone, ligaments, tendons, and the resulting link/joint stiffnesses and damping properties)
- Muscle forces
- ...

4. Include at least *two figures* from the literature review you conducted that highlight key aspects of the biological system. This should include one from each of the following categories:
 1. Figures/drawings of skeleton, anatomy, exoskeleton, body plan, musculature, kinematics
 2. Motion plots, freeze frames of gait cycle, plot of ground reaction forces
 3. ... other aspects of the parameters above.
5. Discuss these papers, highlighting the information you can draw from each. Be specific. Why is each paper valuable? (At least one paragraph per paper)
6. From what you have found, how your project topic novel? (one paragraph)
3. **Estimate Goal Performance Metrics** Identify physical metrics of your design that are missing from background research, or from separate sources. Use your existing knowledge of statics, dynamics, materials, and physics to address these missing pieces.

Example 1: If you know the vertical ground reaction forces during a jump, and the animal's mass, use $F = m/a$ to establish the acceleration of the animal.

Example 2: If you know the maximum height an animal can jump along with its mass and some time-based information about its jump, you could use

$$mgh = 1/2mv_1^2$$

to find the velocity of the animal as it leaves the ground and

$$F = ma \quad (1)$$

$$a = F/m \quad (2)$$

$$v(t) = (F/m)t + v_0 \quad (3)$$

$$v_1 = (F/m)t + 0 \quad (4)$$

$$(5)$$

to find the average vertical ground reaction force over time t required to reach that height.

4. **Assemble a Specifications Table** Collect all the physics-based information you have found from

your references into one place. A well-formatted table may do, with supplementary figures from literature as needed. A specifications table is a handy way to collect parameters. Use SI units. Example below:

Parameter	Unit	Value Range	Reference
Total Mass	kg	.2-.4	[1]
Maximum Landing Force	N	6	calculated above
Maximum Takeoff Force	N	4	[2]
Average Takeoff acceleration	$\frac{m}{s^2}$	13	[3]
...

1. Make sure what source you got each piece of information from, or whether you calculated it yourself.
2. Discuss any changes you made to the values found in your background reading, for safety or performance reasons.

5. **Develop a Kinematic model** for your device using a Python-based script.

This part has been removed and made into a separate assignment

6. **Develop an analogous mechanism** for your source of bio-inspiration in paper or cardboard.

1. **Make the mechanism.** It can be cut by hand, but must clearly communicate where motor(s) will be connected, what touches the ground, and be able to move through its proposed range of motion from (only) motion about the actuators. Take pictures of it in multiple configurations of its gait cycle.
 - The mechanism should use a link / joint topology and the folding approach for making joints that you have learned from this class.
 - Consider using parallel and series mechanisms as they are best suited.
 - Consider both planar and spherical mechanisms as appropriate for your needs.
 - Consider where to eventually place springs.
2. **Draw the proposed mechanism.** Use a vector drawing program (Inkscape, IPE, Illustrator, Draw.io) or 3D modeling software to ensure a professional result.
 - Label each reference frame, including your inertial (Newtonian) reference frame.
 - Include a set of orthonormal basis vectors for each frame $(\hat{n}_x, \hat{n}_y, \hat{n}_z)$, $(\hat{a}_x, \hat{a}_y, \hat{a}_z)$. It is best practice to align one of the basis vectors (like \hat{a}_x) with each rigid link.
 - variable names for each state variable $(\theta_1, \theta_2, \dot{\theta}_1, \dot{\theta}_2, \dots)$
 - geometric values such as link lengths (l_1, l_2, \dots)

Save this figure for reuse later. You will need to add mass and inertial information as well as system stiffness information, so make sure you do your work in a way that permits reusing and modifying the figure.

7. System Identification

The purpose of this part is to create a plan for identifying key model parameters that teammates will be able to execute individually, and then contribute back to their team's modeling effort. This should include aspects from the following:

- Actuator parameters – resistance, inductance, inertia, damping, mass, K_v / K_τ , gearing – fit against experimental data.

- The mass and inertia properties of key parts of your proposed system, modeled and verified.
 - The stiffness and damping characteristics
 - of your team's joints, as fabricated.
 - of your team's links, as fabricated.
 - of a key subsystem, as fabricated.
 - of a discrete energy storage component.
 - Friction estimations and a model fitting process between key materials undergoing contact interactions
 - ...other ideas approved by your professor
1. Identify and discuss the various parameters you plan to model in your simulation. Discuss your plans for experimentally obtaining each of those values, and the model you would like to use for describing each phenomenon.
 2. Create a table with at least four system identification experiments you will run, and an assigned team lead for each experiment.

Item	Sam	Jo	Pat	Stevie
Servo Characterization	x			
Link Stiffness Experiment		x		
Joint Stiffness Experiment			x	
Mass and inertia calculations and validation of main body				x

Individual experiments will be assigned to each team member as part of an upcoming individual assignment.

8. Project Part 2 Roadmap

Finally, plan the upcoming tasks and roles for the other team activities. Write up your plan for the following:

1. Identify and discuss the materials you plan to use in fabrication, and key design decisions, such as how you plan to fabricate parts. Decide who will be obtaining those materials and distributing them.
2. Identify and discuss how you plan to prototype your system and assign one person to do that
3. Identify and discuss how you will collect system-level motion or force data for validation, including:
 - method (IMU, video, discrete joint sensors, force/torque sensing)
 - data extraction approach
 - how you plan to characterize performance. What metrics will you use and what experiments do you need to measure that performance?
 - how you plan to visualize your data.

Note: We are distinguishing from component level model fitting, which should come before you add elements to your model, and verification / validation experiments, which should come after you have built your final device.

4. Identify and Discuss your plan for shared simulation tasks:
 - who will be working with the code
 - adding model fitting routines
 - filtering, interpolating and otherwise massaging input data.

- optimization approach
- 5. Identify and discuss any reporting tasks that may be needed
 - compiling information into a report (may be combined with the simulation if using Jupyter)
 - managing the GIT repository
- 6. Split each of these tasks to the individuals on your team and visualize task assignments in a table.

1.3 Submission

Please include a report with the following

1. The requested steps of the procedure, in paragraph form (no sentence fragments).
2. Answers to the discussion points above
3. Plots & Figures
4. Bibliography in IEEE format
5. Code - any code created by your team to in the generation of this report. If you are using a jupyter notebook, to generate the whole report, you can supply your code inline.

Please follow the "Submission Best Practices" document posted the course website. This assignment should be submitted as a .pdf document and/or a jupyter notebook (.ipynb). If submitted as a notebook, make sure it is fully compiled. This can be done by opening the file in the jupyter browser and in the top jupyter menu selecting "Kernel" --> "Restart and Run All". Attach a pdf version of the compiled notebook as well.

You will also present your team's design in class

1.4 Suggestions

- Be creative in your search terms, and make sure to report the search terms that yielded good results.
- Write down and use the keywords identified from class.
- Collect your references in a bibliography program like Zotero or Mendeley for easier handling.

*
